

## A Cost Comparison Between Standard Plan A and P-1100 Retrofits.

This study is a cost comparison between the Standard Plan A design system and the FEMA P-1100 design system. See Appendix A for Standard Plan A calculations.

The following pages contain tabulated price and design comparisons between the two design systems when applied to the exact same house i.e. the weight classification, square footage, seismic design category and the number of stories are exactly the same.

The pricing per piece of hardware and per linear foot of plywood shown below is based on Bay Area Retrofit's current price schedule.

Pricing	
5/8" Bolts	\$77 each
Type A Connector URFP	\$135 each
Type B Connector FRFP	\$135 each
12" Rip Cut Shim	\$50 each
24" Cross Cut Shim	\$90 each
48" Rip Cut Runner	\$175 each
Type E Connector (L90)	\$39 each
Plywood < 4 feet	\$90 plf
Plywood > 4 feet	\$165 plf
Tie Downs	\$215 each

Rip cut shims are shims that cut parallel to the grain. Cross cut shims are cut perpendicular to the grain. Rip cut shims are much more labor intensive which is why they cost more. A 48" rip cut runner is a 48" shim that is part of Detail 3, Sheet D2.

Hardware and plywood capacities are rated according to the SDPWS, NDS, and the Simpson StrongTie catalog.

Capacities	
5/8" Bolts in 2" Close Grain Redwood	1400#
Type A Connector (URFP)	1530#
Type B Connector (FRFP)	960#
Type E Connector (L90)	925#
Light Construction Rated Plywood	380plf
Medium Construction Rated Plywood	490plf
Standard Plan A 3" o.c. Structural 1 Plywood	550plf
Heavy Construction Rated Plywood	640plf

Seismic Design Coefficient in Standard Plan A is 0.186.

All house weights derived from Standard Plan A Calculations. See Appendix B

P-1100 Seismic Design Coefficient for mudsill connectors and framing anchors = 0.393 ((0.562 x .7)

Seismic Design Coefficient in P-1100 for plywood = 0.262 (0.375 x 0.7)

## The Bay Area's Housing Stock.

EARTHQUAKE RETROFIT SCHEDULE										
Weight Category	Total Area in Square Feet	Mark row that applies <input checked="" type="checkbox"/>	Length Each of Two Braced Wall Sections Along Each Perimeter Wall					Wood Structural Panel		
			Cripple Wall Height							
			up to 1'	1'-1" to 2'	2'-1" to 4'-0"		4'-1" to 6'-0"			
			Without Tie-downs	Without Tie-downs	Without Tie-downs	With Tie-downs	Without Tie-downs	With Tie-downs		
1-Story Light Construction	up to 800		8.0'	8.0'	10.7'	8.0'	12.0'	8.0'		
	801 to 1000		9.3'	9.3'	12.0'	9.3'	13.3'	9.3'		
	1001 to 1200		10.7'	10.7'	13.3'	10.7'	16.0'	10.7'		
	1201 to 1500		12.0'	12.0'	14.7'	12.0'	17.3'	12.0'		
	1501 to 2000		14.7'	14.7'	17.3'	14.7'	21.3'	16.0'		
	2001 to 2500		18.7'	18.7'	20.0'	18.7'	24.0'	18.7'		
	2501 to 3000		21.3'	21.3'	22.7'	21.3'	26.7'	21.3'		

The cripple wall of this home appears to be slightly less than 4 feet tall. Applying P-1100's earthquake retrofit schedule, 29' 3" (without tie downs) or 24' (with tie downs) of shear walling is required. There is not enough available foundation to do this. This is one of the problems with FEMA P-1100. (Remember TWO lengths of structural panel are required on each wall line)

## The Comparison Process

In the following pages the FEMA P-1100 applications are identified by “P-1100” at the beginning of the house description.

Standard Plan A retrofits are identified by “Standard Plan A” at the beginning of the house description.

 Seismic Retrofit Contractor  
 (510) 548-1111

16 Type A Connectors =	\$2,160
(16) 2 x 4 x 24" Cross Cut Shims	\$1,440
28 L90s	\$1,092
<b>Total</b>	<b>\$4,692</b>

Base shear = 4,268#on each wall line.

Component

Shear resistance on each wall line

Type A Connector 960#	6,120# each wall line
30" Cross Cut Shims with (4) 1/4" SDS screws	6,400# each wall line
L90s -	6,475# each wall line

**Comparison**

**P-1100-1,350sf – No Cripple Wall - Light Construction – Detail 3, Sheet D2 \$26,264**

Component	Shear resistance on each wall line
Type B Connector 960#	15,360# each wall line
4' Rip Cut Runners. No load rating	<u>Does not meet 2" min. penetration requirement</u>
L90s -	23,125# each side

**Standard Plan A - 1,350sf - No Cripple Wall - Light - Construction – 2' \$4,692**

Base shear = 4,268#on each wall line.

Component	Shear resistance on each wall line
Type A Connector 960#	6,120# each wall line
30" Cross Cut Shims with (4) 1/4" SDS screws	6,400# each wall line
L90s -	6,475# each wall line

**COST COMPARISON**

**P-1100 Detail 3, Sheet D2**

Type B Connector	64	\$8,640
4' Rip Cut Runners.	64	\$6800
L90s	100	\$3900
	<b>Total</b>	<b>\$19,340</b>

**Alternate SPA Type A Connector**

Type B Connector	16	\$2,160
2' Cross Cut Shims	16	\$1,440
L90s	28	\$1092
	<b>Total</b>	<b>\$4692</b>
	V =	0.186 W

## Conclusion

On average FEMA P-1100 retrofits cost three times as much as retrofits designed using Standard Plan A. Seismic retrofits are, and will continue to be, voluntary. This has been local jurisdiction policy all over the state for decades.

Homeowners must therefore be enticed by reasonable cost rather than discouraged by high cost retrofits. High cost is the number one disincentive homeowner face when deciding whether or not to improve the lateral force resisting system of their home.

## The Seismic Design CO-efficient Impact on Cost

The seismic design Coefficient in FEMA P-1100 for plywood is 0.262.

The seismic design Coefficient in FEMA P-1100 for bolts and framing anchors is 0.393.

The seismic design Coefficient in Standard Plan A is 0.186 no matter which retrofit component is considered.

This is why bolt, plywood, and L90 capacities never match in P-1100. For example, in this P-1100 retrofit for a 3.150sf - Two Story - 5' Cripple Wall - Medium Construction home the difference in capacities and quantities vary greatly. This has an enormous impact on cost. .

Component	FEMA P-1100	Total capacity and cost
(100) 5/8 Bolts-	150,000# = \$7,700	
(168lf) 490 plf Plywood-	82,320 # = \$27.720	
(216 ) L90s	199,800# total = \$8,424	
<b>TOTAL COST</b>	<b>\$43,844</b>	

This is unaffordable for most homeowners.

On the other hand, the earthquake resistance of bolts, plywood, and L90s are practically the same when Standard Plan A's Seismic Design Coefficient of 0.186 is applied equally to all components. The matching of capacities reduces cost considerably.

Component	Standard Plan A	Total capacity and cost
(32) Bolts- 1500#	48,000# = \$2,464	
(96lf) 550plf Plywood-	52,800# = \$15,840	
(56) L90s -	51.800# = \$2,184	
<b>TOTAL COST</b>	<b>\$20,488</b>	

This is affordable for most homeowners.

## Conclusion

The Seismic Design Coefficient in P-1100 drives the cost beyond what most homeowners can afford and will cause homeowners to revert to other design systems such as such as Standard Plan A or self-styled systems contractors have created themselves.

If this standard is not made more affordable it will never be used to reduce problems in found voluntary seismic

## Appendix A

### Standard Plan A's Engineering Background – By Jim Russell

Here are the [complete calculations](#).

The following calculations determine the seismic load demand to cripple walls and foundation sill plates for conditions commonly found in existing wood-framed residential buildings located in the San Francisco Bay Area. These demands are the basis for the cripple wall bracing and foundation sill anchorage requirements contained in the East Bay and Peninsula Chapter of ICC Seismic Retrofit Provisions. Certain assumptions are made in the calculation of these demand loads. They include:

1. Wood structural panels are used to brace the cripple walls, and the buildings are limited to a maximum of two stories. Therefore, the R factor used is 5.5. (2001 CBC Table 16-N)
2. The Redundancy Factor  $\rho$  ( $\rho$ ) = 1.0, because the cripple wall bracing lengths along each exterior wall in each axis are equal, or are nearly equal. (2001 CBC Sec.1630.1.1)
3. The Near Source Factor ( $N_a$ ) = 1.3, to account for buildings that are located between 4 and 10 kilometers of a Type A fault. This value is less than the maximum  $N_a$  = 1.5 specified for locations 2 kilometer or less from a Type A fault, but is greater than the  $N_a$  = 1.1 value permitted for buildings that are, 1) located on soil classified not greater than type SD, 2) are not defined by the code as being irregular, and 3) have  $\rho$  = 1.0. (CBC Sec.1629.4.2 and Tables 16-L, 16-M, and 16-S)

4. New resisting elements are located at the building perimeter only, therefore, one-half of the total seismic load in each axis is resisted by each of two parallel perimeter wall lines.
5. No reduction from current code force levels is being taken, as is permitted by Section 301.3 of the Guidelines for Seismic Retrofit of Existing Buildings. (ICBO, 2001)

Certain assumptions are made with respect to the capacities of the new materials added to strengthen the buildings. They include:

1. Allowable stresses are increased by a factor of 1.33 for short term seismic loads, or are based on tabular values already adjusted for seismic loading (2001 CBC Table 23-II-I-1).

The following assumptions have also been made regarding the construction of the houses:

1. The floor to ceiling wall height is 8 feet.
2. The roof slope is 4:12, with gable ends occurring on the short (transverse) side, and two foot eave overhangs on all sides.
3. Four Cases of exterior and interior wall finish and roofing are considered.

- A) **Lightweight roofing (5 psf) of wood shake, wood shingle, or composition shingle, exterior wood sheathing or board finish, and 1/2" gypsum wallboard interior finish.**
- B) **Lightweight roofing, exterior wood sheathing or board finish, and gypsum lath and plaster interior finish. This is considered the definition of "Light Construction"**
- C) **Lightweight roofing, cement plaster (stucco) exterior finish, and gypsum lath and plaster interior finish.**
- D) **Lightweight roofing, cement plaster (stucco) exterior finish, and gypsum wall board interior finish.**

Category D was missing from the original calculations and I added it based on the weights defined elsewhere in the calculations. These calculations look at 3 different footprint sizes:

- For one-story buildings the footprint sizes are:
  - 1) 30 feet by 40 feet (1,200 square feet)
  - 2) 30 feet by 50 feet (1,500 square feet)
  - 3) 36 feet by 56 feet (2,016 square feet)
- For two-story buildings the footprint sizes are:
  - 1) 30 feet by 30 feet (1,800 square feet)
  - 2) 30 feet by 40 feet (2,400 square feet)

3) 30 feet by 50 feet (3,000 square feet)

## Appendix B

I averaged the weights of these footprints and created this table. These weights are used in determining Standard Plan A base shear.

<p><b>Light Construction</b></p> <p><b>ROOF: SHNGLES</b></p> <p><b>SIDING: WOOD</b></p> <p><b>WALLS: DRYWALL</b></p> <p><b>ONE STORY- 34 psf</b></p> <p><b>TWO STORY – 29.5 psf</b></p>	<p><b>Medium Construction</b></p> <p><b>ROOF: SHNGLES</b></p> <p><b>SIDING: STUCCO</b></p> <p><b>WALLS: DRYWALL</b></p> <p><b>ONE STORY- 41 psf</b></p> <p><b>TWO STORY-36.5 psf</b></p>
